**ABSTRACT**

The effect of watermelon rind powder addition on the functional, pasting and microbiological quality of Sorghum based *mumu* was evaluated. Sorghum-based *mumu* was prepared from composite flours of 85:15, 75:15, 70:15 and 65:15% roasted sorghum flour and roasted partially defatted groundnut flour respectively and included with 0, 10, 15 and 20% watermelon rind powder respectively which were known as sample A, B, C and D accordingly. Subsequently, the functional, pasting properties and microbial quality was assessed. Functional properties values; Bulk density (0.89 to 0.80mg/100g), reconstitution index (4.99 to 4.89) and swelling index (2.35 to 2.20) decreased significantly (p < 0.05) with increase in watermelon powder addition while water absorption (10.36 to 10.97g/g), oil absorption (10.33 to 10.79) and foam capacities (12.46 to 13.85%) increased with increase in watermelon rind powder. The pasting properties; peak (302.22 to 292.44 RVU), trough (156.44 to 150.00 RVU) and Final viscosities (412.69 to 400.76RVU), and breakdown (149.95 to 140.59RVU) decreased significantly (p < 0.05) with increased in watermelon

*Corresponding author: Email: stephenter09@gmail.com;*
rind powder while setback viscosity (101.05 to 115.59RVU), pasting temperature (59.32 to 62.02°C) and pasting time (4.93 to 5.13mins) increased. Microbial analysis revealed the following ranges: Total viable count, 0.5x10^2 to 1.0x10^2 cfu/g, fungi count of 6.1x10^1 - 9.9x10^1 cfu/g and no coliform was detected. Overall, addition of watermelon rind powder showed good functional, pasting and microbiological qualities of sorghum based mumu.

Keywords: Mumu; sorghum; watermelon rind; pasting.

1. INTRODUCTION

Mumu is a Nigerian cereal-based food product processed from roasted sorghum, millet or maize and consumed particularly by Tiv people (adults and children). Mumu is in powdered form and can be reconstituted in cold water with sugar to taste. It can be eaten at any time of the day and served as energy giving food. The class of people that consume mumu are mostly low income groups that cannot afford animal protein, therefore there is need to enrich mumu with plant proteins [1].

Sorghum, one of the cereals for production of mumu is rich in carbohydrate but low in protein and other micronutrients [2]. Mumu food product has gained a lot of attention among the over four million Tiv people and hence, the need to supplement it with locally available sources [3].

Groundnut also called Peanut is a legume crop that belongs to the family of Fabaceae, genus Arachis, and botanically named as Arachis hypogaea. Groundnuts are consumed in many forms such as boiled peanuts, peanut oil, peanut butter, roasted peanuts, and added peanut meal in snack food, energy bars and candies [4]. Groundnut, which is a rich source of protein and essential amino acids, can help in preventing malnutrition [5]. Blending of sorghum with groundnut will result in mumu with high protein content but low in micronutrient content [2].

Watermelon (Citrullus lantus) rind is the greenish outer covering of the fleshy, succulent sweet pulp and is usually wasted after consumption of the pulp. Watermelon rind is a good source of vitamins such as vitamin (A, C, B6, B2 and B3) and minerals such as (phosphorous, calcium, sodium, iron and zinc) [6]. Watermelon is also high in citrulline, an amino acid the body make use of to make another amino acid, arginine (used in the urea cycle to remove ammonia Cal from the body) [7]. The research by Gbaa et al., [8] has shown that blending sorghum/groundnut mumu with watermelon rind powder had significantly improve the nutritional value of the product in terms of its macro and micronutrients content thereby improving the nutritional status of the consumers.

When starch-based foods are heated in an aqueous environment, they undergo a series of changes known as gelatinization and pasting. These are two of the most important properties that has effect on quality and aesthetic concerns in the food industry, since they affect texture and digestibility as well as the end use of starchy foods [9]. The functional properties of a food material affect how it interacts with other food components and determines its application and end use. Therefore, food items with good functional properties can be easily incorporated into other foods and will yield good quality and acceptable end products [10]. Pasting characteristic measures the viscosity of flours over a range of temperature and pressure and are used for predicting the ability of flour to form a paste when subjected to heat application in the presence of water [10,11].

The aim of this study therefore is to determine how the addition of watermelon rind powder will affect the functional, pasting and microbiological quality of the mumu product.

2. MATERIALS AND METHODS

2.1 Sources of Raw Materials

Yellow sorghum (Sorghum bicolor) and Groundnut (Arachis hypogaea) were purchased from Wurukum Market, Makurdi. Locally available fresh watermelon free from physical disorder was purchased from railway market, Makurdi and the rinds were collected after the flesh has been separated.

2.2 Samples Preparation

2.2.1 Preparation of roasted sorghum flour

Roasted sorghum flour was prepared according to the method described by Ingbian and Adegoke [1] with slight modification, without fermentation.
of the grains. Sorghum grains were sorted and winnowed to remove grain stalk, sticks and remaining husk. The grains were further subjected to visual screening to remove foreign particles such as stones. This was followed by washing with water to remove dust, soil particles and any over floats. Damaged, diseased or discolored grains as well as immature or sprouted grains were discarded. Cleaned sorghum grains were oven roasted at 150°C for 60 min. The roasted grains were kept under silica gel to avoid moisture re-absorption until when required for milling and mixing for formulation of blends. A hammer mill was used to mill the roasted grains and a sieve of 0.5 mm was attached to collect the milled product.

2.2.2 Preparation of roasted partially defatted groundnut flour

Roasted defatted groundnut flour was prepared by the method described by Adjou et al. [12] with modification that the cake was milled into flour. The groundnuts were sorted to get rid of foreign matter, and roasted at 150°C for about 6-8 minutes and then allowed to cool and the bran was removed and milled to obtain fine flour. To extract oil from groundnut flour, hot water extraction method was used. The flour was pressed in the mortal and pounded gently with addition of hot water till the oil was collected by pressing in muslin cloth. It was shaped and deep fried to form cake. The cake was cooled and milled into flour.

2.2.3 Preparation of watermelon rind powder

Watermelon rind powder was prepared as describe by Lee-Hoon and Norhidayah [13]. Watermelon (Citrullus lanatus) rind was separated from washed fresh fruits manually with a stainless knife. The rind was cut into small pieces before drying in a hot air oven at 50°C for 24 h. The only modification was that freshly cut watermelon rind of 8 mm thickness were placed on aluminium foil in hot air oven at constant air velocity (0.8 m/s). The dried slices of watermelon rind were then ground in a laboratory mill and further sieved through a 0.5 sieve screen to fine powder and kept in an airtight plastic container and stored in a cool dry place prior to use as shown in Fig. 1.
2.2.4 Formulation of blends
Four blends, A, B, C and D were formulated using different ratios; Sample A was comprising 85% roasted sorghum flour, 15% roasted defatted groundnut flour and 0% watermelon rind powder which served as the control; sample B comprising 75% roasted sorghum flour, 15% roasted defatted groundnut flour and 10% watermelon rind powder; sample C comprising 70% roasted sorghum flour, 15% roasted defatted groundnut flour and 15% watermelon rind powder and sample D comprising 65% roasted sorghum flour, 15% roasted defatted groundnut flour and 20% watermelon rind powder.

2.2.5 Preparation of Mumu product
The resulting mumu from four blends A, B, C and D were prepared by reconstitution of powdered form mumu in cold water with desired consistency and sugar added to taste.

2.3 Determination of Functional Properties of Mumu
2.3.1 Determination of bulk density
Bulk density was determined by method described by Onwuka [14] 10 ml capacity graduated measuring cylinder and filled gently with each sample. The bottom of the cylinder was gently tapped on a laboratory bench several times until there was no further diminution of the sample level. Bulk density was calculated as shown below:

\[
 Bulk\ Density = \frac{\text{Weight of sample (g)}}{\text{Volume of the sample (ml)}} \quad (1)
\]

2.3.2 Determination of water and oil absorption capacity
The oil and water absorption capacity was determined according to the method of Onwuka [14]. 1 g of sample was added to distilled water in 10 ml distilled water/vegetable oil in a conical flask. The mixture was allowed to stand for 30 minutes at room temperature and then transferred into a graduated centrifuge tube. It was centrifuged at 500rpm for 30 minutes. The volume of water/oil absorbed (total volume-free volume) was multiplied by the density of water absorbed or retained per gram of sample.

\[
 \text{Water/oil absorption capacity (g/100 g) = } \frac{\text{Density of water/oil X Volume of Water or oil absorbed}}{\text{Weight of Sample}} \quad (2)
\]

2.3.3 Determination of Foaming Capacity (FC)
The foaming capacity of the four blends was determined as described by Onwuka [14]. Two grams (2 g) of flour sample was blended with 100 ml distilled water in a blender and the suspension was whipped at 1600rpm for 5 minutes. The mixture was poured into a 250 ml measuring cylinder and the volume was recorded after 30 seconds.

\[
 \text{Foaming Capacity} = \frac{\text{volume after whipping - volume before whipping}}{\text{Volume before whipping}} \times 100\% \quad (3)
\]

2.3.4 Determination of Swelling Index (SI)
The method as described by Onwuka [14] was used in the determination of the swelling index. One gram (1 g) of the flour sample was weighed into 10 ml graduate cylinder. Five milliliters (5 ml) of distilled water was carefully added and the volume occupied by the sample was recorded. The sample was allowed stand undisturbed in water for one hour (1 h) and the volume occupied after swelling was recorded and calculated as:

\[
 \text{Swelling index} = \frac{\text{Change in Volume of sample}}{\text{Original Volume of Sample}} \quad (4)
\]

2.3.5 Determination of Reconstitution Index (RI)
The reconstitution index of the flour sample was determined according to method described by Onwuka [14] Five grams (5 g) of the flour sample was dissolved in 50 ml of boiling water. The mixture was agitated for 90 seconds and was transferred into a 50 ml graduated cylinder and the volume of the sediment was recorded after settling for 30minutes.

\[
 \text{Reconstitution index} = \frac{\text{Volume of sediment}}{\text{Weight of Sample}} \quad (5)
\]

2.4 Determination of Pasting Properties of Mumu
Pasting properties of mumu samples were determined according to AACC [15] using the rapid visco analyser (RVA). The composite flour sample (3.5 g) was weighed and dispensed into the test canister. Distilled water (25.0 ml) was thereafter dispensed into the canister (14% moisture basis). The visco analyser was switched on and the pasting performance of the flour was automatically recorded on the graduated sheet of the instrument.

2.5 Microbial Analysis

2.5.1 Determination of Total Viable Count (TVC)

The total viable count was determined according to the method of [16]. The samples were inoculated using nutrient agar after the serial dilution of the samples had been obtained with 1 g of each sample. Pour plate method was used. The colony count was done after 24 h of incubation at 37°C using a colony counter and the number of colonies calculated using the following method:

\[
\text{TVC (CFU/g) = \frac{\text{Number of colonies x Original concentration}}{\text{(Dilution factor x volume of inoculums)}}.}
\]  

(6)

CFU = Colony Forming Unit

2.5.2 Determination of total Mould Count (MC)

The mould count was determined using the method described by Prescott et al. [16]. After the serial dilution of the samples, they were inoculated using Sabauroud Dextrose Agar (SDA). Pour plate method was used. The colony count was done after 72 hours on incubation at 37°C using a colony counter and the number of colonies calculated using the following method:

\[
\text{Mould count (CFU/g) = \frac{\text{Number of colonies x Original concentration}}{\text{(Dilution factor x volume of inoculums)}}.}
\]  

(7)

CFU = Colony Forming Unit.

2.6 Statistical Analysis

Data obtained was subjected to Analysis of Variance (ANOVA) followed by Tukey’s Least Significant Difference (LSD) test to compare treatment means; differences was considered significant at 95% (P≤0.05) (SPSS Version 21 software).
3. RESULTS AND DISCUSSION

3.1 Effect of Watermelon Rind Powder (WRP) Addition on Functional Properties of Sorghum Based Mumu

Table 2 shows the effect of WRP addition on the functional properties of sorghum based mumu. The bulk density of the samples decreased significantly (P<0.05) as addition of watermelon rind powder increase. Sample A had the highest bulk density (0.89 g/ml). The values obtained were lower than values (0.97-0.92 g/ml) for corn starch/sorghum flour and (0.98-0.96 g/ml) for sorghum/African yam bean flour reported by Okoye et al. [17] and Okoye et al. [18] respectively. The bulk density of flours is important as it affects mixing, packaging, and transportation. Nutritionally, low bulk density is advantageous because it engenders consumption of more quantity of the lighter food item and this translates into more nutrients for the consumer [19].

Water absorption capacity of mumu samples showed significant (p≤0.05) increased as the watermelon rind powder addition increases. The values ranged from 12.36 to 13.31 g/g. Similar increased in the water absorption capacity of cowpea- water yam flour, cassava- sorghum flour meals, cocoyam-soybean-crayfish flour blends has been reported by Otunnola and Afolayan, [20], Oti and Akobundu [21]; Perez and Perez [22] respectively. The increased in water absorption capacity could be due to high water absorption capacity of WRP which is in agreement with finding by Olaitan et al. [23]. And on the other hand the difference in protein concentrations and the degree of interaction of such proteins with water [24]. Increase in water absorption capacity improves the structural matrix for holding water, sugars and other components [25]. According to Onyerekua and Adeye [26] high water absorption capacity is desirable for the improvement of mouth feel and viscosity reduction in food product.

The oil absorption capacity of the mumu samples showed significant (p≤ 0.05) increased as the level of watermelon rind powder addition increases. The values ranged from 10.31 to 10.97 g/g. The possible explanation of this may be due to dilution factor by fibre from addition of high fibre watermelon rind powder. Wang et al. [27] reported that oil absorption capacity of cereals increases with increased in fibre. Apart from that, increased OAC means that the food material has high hydrophobic proteins; the more hydrophobic proteins demonstrate superior binding of lipids [28].

There was significant decreased (p<0.05) in the values of reconstitution index as addition of watermelon powder increases. The values ranged from 4.99 – 4.87. Although the samples easily reconstituted, the decrease in reconstitution index was an indication that increasing the content of the WRP in the mumu blends increases water absorption capacity which in turn improves the reconstitution ability of the mumu blends. Similar observations had been reported by Adebowale et al. [29] and Adegunwa et al. [30].

The mumu samples decreased significantly (p≥0.05) in swelling capacity as the level of WRP addition increased. The values of the swelling index ranged from 2.55 to 2.20. Sample A has the highest swelling index of 2.35. This is in agreement with values (2.48 – 2.30 g/ml) obtained by Akajiaku et al. [31] in sorghum/wheat noodles. The result could be due to increase in protein content of the food product since Wang et al. [32] reported that increasing amount of protein could inhibit the starch granules from swelling.

The foaming capacity increased significantly (p<0.05) with increased WRP addition in the mumu blends. The values ranged from 12.46 to 13.85%. This result is higher than the values obtained from wheat/ groundnut protein concentrate flour (5.25 – 9.20%) recorded by Ocheme et al. [10]. The observed foaming capacity increased could be as a result of increased protein content since addition of watermelon rind powder has been reported to increase protein content of mumu [13]. Brou et al. [33] also reported that foaming capacity is positively correlated with protein content.

3.2 Effect of WRP Addition on the Pasting Properties of Sorghum Based Mumu

Table 3 shows effect of watermelon rind powder addition on the pasting properties of sorghum-based mumu. Peak viscosity is the maximum viscosity developed during or soon after the heating portion. It is the index of the ability of starch to swell freely before their physical breakdown [29,34]. Peak viscosity decreased significantly (p<0.05) from 302.22 to 292.44 RVU as the level of WRP addition increased. Peak viscosity has been reported to be correlated with

water binding capacity of starch which takes place at equilibrium point between swelling which causes an increase in viscosity while rupturing and realignment cause its reduction [35]. According to Osungbaro [36], high peak viscosity is an indication of high starch content. High peak viscosity values noted in the study is of processing advantage and has been reported to be significant in the preparation of stiff dough products made from cereal flours [37].

Trough viscosity is the maximum viscosity value in the constant temperature phase of the rapidis visco analyzer pasting profile. In simple terms, trough viscosity is the point at which the viscosity reaches its maximum during either heating or cooling processes. It measures the ability of the paste to withstand break down during cooling [22]. Trough viscosity significantly (P<0.05) decreased as level of addition of WRP increases. The values ranged from 156.44 to 150.00 RVU. This result is similar to the range obtained (80.30 to 117 RVU) of Ofada rice [37] and 80 to 159RVU of African yam bean and brown cowpea seeds composite flour [38] but lower than trough viscosity values (820 to 536 RVU) of wheat and groundnut concentrate flour blends [10]. The significant high trough viscosity obtained in this study indicates the tendency of the mumu samples to break during cooking.

The breakdown viscosity is an index of the stability of the starch and a measure of the ease with which the swollen granules can be disintegrated [39]. There was significant (P<0.05) difference in breakdown viscosity. The values ranged between 149.95 to 140.59RVU. Sample A had the highest breakdown viscosity. The result of this study is similar the range 32.00-151.00 RVU for cereal grains reported by Adebayo, [40] and higher than values 2.38-126.59 RVU for acha, defatted soy bean and groundnut flour [41]. The higher the breakdown viscosity, the lower the ability of starch in the flour samples to withstand heating and shear stress while lower breakdown value indicates that the starch in question possess cross-linking properties [42].

Final viscosity is commonly used to define the quality of particular starch-based flour since it indicates the ability of the flour to form a viscous paste after cooking and cooling. It also gives a measure of the resistance of the paste to shear force during stirring [29,43]. There was significant (P<0.05) decreased in final viscosity as level of addition of watermelon rind powder increases. The values ranged from 412.69 to 400.76 RVU. Sample A has the highest Final Viscosity. The final viscosity values obtained in this study are higher than 190.3 to 261 RVU reported for Ofada rice variety [37]. This result indicates that the final viscosities are important in determining the ability of the sample materials to form gel during processing [44].

The set back value of the food indicates the tendency of starch granules to retrograde on cooling [19]. There was significant (P<0.05) difference in the setback viscosity of the mumu samples as addition of watermelon rind powder increased. The setback value of the blends ranged between 115.59 to 101.05 RVU. The result of this research is similar to the range 115.37 to 139.49 RVU observed for cassava starch/mushroom [45]. Higher setback results indicate lower retrogradation during cooling of products [46]. When starch is heated in the presence of water and subsequently cooled, the disrupted amyllose and amylopectin chains can gradually re-associate into a different ordered structure in a process termed retrogradation. Starch retrogradation is usually accompanied by a series of physical changes such as increased viscosity and turbidity of pastes, gel formation, exudation of water [47].

Pasting temperature is the temperature at which the first detectable increase in viscosity is measured and it is the index characterized by the initial change due to swelling of starch [48]. There was significant (P<0.05) increased in pasting temperature as inclusion of watermelon rind powder increases. The values ranged from 59.32 to 62.02ºC. The result obtained in this study is lower than range of 81.43 to 83.29ºC for cassava starch/mushroom [45]. A high pasting temperature usually indicates the flour has high water absorption capacity [48]. Therefore observed lower pasting temperature of sample A could be as the result of low water absorption capacity of the blend.

Pasting time is the measure of the cooking time [49]. There was significant (P<0.05) increased in pasting time as inclusion of watermelon powder increases. The pasting time ranged from 4.93 to 5.13 min. The result is similar to the values 4.79 to 5.75min for cassava starch/mushroom observed by Ojo et al. [45]. The result indicates that sample A with pasting temperature of 4.93minutes requires shorter time to
3.3 Microbiological Quality of Sorghum Based Mumu

The microbial examination of the products revealed different values for total viable count and fungi count as shown in Table 4. The total viable count ranged from 5.00 to 1.0x10^2 cfu/g, while the fungi count ranged between 61 to 99 cfu/g. The contamination could have occurred during cooling and before packaging. Fungi such as yeast are commonly present as contaminants in cereals and can probably be attributed to the low value of the pH which creates ideal conditions for yeast growth [50]. The presence of micro flora may also be due to availability of more nutrients for microbial proliferation and enhanced metabolic activities [51]. However, the samples had low levels of bacteria and mould growth. No coliform was detected. The microbial counts were within the permissible limit set by the Standard Organization of Nigeria, which states that the counts of aerobic bacterial must not exceed 100cfu/g. Thus the consumption of these products may not be fraught by the danger of contacting any food borne disease.

4. CONCLUSION

Addition of watermelon powder to sorghum based mumu produced good effect on the functional and pasting properties as well microbial safety of the product. Bulk density, swelling index and reconstitution of the mumu reduced significantly \( p < .05 \) with increasing level of watermelon rind powder while, water absorption, oil absorption and form capacities increased. Peak time, peak, trough, breakdown, final, viscosities of the flour blends decreased with increase percentage of watermelon rind inclusion while the setback viscosity, pasting temperature and pasting time increased. The mumu samples blends had low levels of bacteria and mould growth. No coliform was detected Thus the consumption of these products may not be fraught by the danger of contacting any food borne disease.
